

Photosynthesis: A Simple Biological Concept

Photosynthesis is the process by which plants, algae, and some bacteria use sunlight to make their own food.

During photosynthesis, plants take in carbon dioxide from the air and water from the soil. Using energy from sunlight, they convert these materials into glucose (a type of sugar) and oxygen.

The glucose provides energy for the plant to grow and survive, while the oxygen is released into the atmosphere and is essential for many living organisms.

Photosynthesis is important because it forms the foundation of most food chains and helps maintain oxygen levels on Earth.
